# Scientific consensus and social controversy: exploring relationships between students' conceptions of the nature of science, biological evolution, and global climate change

B Elijah Carter<sup>1,2\*</sup> and Jason R Wiles<sup>1,2,3,4</sup>

## Abstract

**Background:** It is overwhelmingly acknowledged by the scientific community that evolution and global climate change (GCC) are undeniably supported by physical evidence. And yet, both topics remain politically contentious in the United States. It is thought that students' conceptions of the nature of science (NOS) may be key factors in their attitudes towards evolution and GCC. Our study explored this hypothesis guided by the following questions: Do changes in NOS conceptions correlate with changes in attitudes towards evolution or GCC? If there are correlations, are they similar for evolution and GCC? What demographic factors affect these correlations?

**Methods:** Previously-developed tools were used to measure students' conceptions of the nature of science and attitudes towards evolution, while national public opinion poll questions were used to measure attitudes towards GCC. Demographic questions were produced to target factors thought to influence attitudes towards evolution or global climate change. Overall sample size was N = 620. Principle components analysis was used to determine which variables accounted for the most variation, and those variables were analyzed using correlation tests, ANOVA, and ANCOVA to test for significant correlations and interaction effects.

**Results:** Changes in students' attitudes towards evolution and global climate change were both positively correlated with shifts in conceptions about the nature of science. Attitudes towards evolution were negatively correlated with religiosity. Knowledge of evolutionary science was positively correlated with attitudes towards evolution, but knowledge about GCC was not significantly correlated with attitudes towards GCC. The strongest correlates of GCC attitudes were political leanings.

**Conclusions:** Findings support the hypothesis that a better understanding of NOS may lead to changes in attitudes towards politically contentious ideas that are not scientifically contentious. Though attitudes towards evolution correlated strongly and significantly with a number of other factors including knowledge of evolutionary science and religiosity, expected non-political correlates with attitudes towards GCC were absent. Giving students a good conception of the modern nature of science may lead to views that are closer to those of the scientific community. This study provides novel evidence of a linkage between student acceptance of evolution and attitudes towards GCC, that is, NOS conceptions.

**Keywords:** Evolution education; Global climate change; Nature of science; Politicization

## Background

Evolution, as defined broadly and narrowly, includes the fact that the living organisms of today differ from those of the past, the evidence-based inference that the diversity we now see has arisen via descent with modification from an ancient ancestry, and the organic mechanisms through which biological change occurs (Eldredge 2005; Gould 1981; Scott 2004; Wiles and Alters 2011). As it is defined in the textbook assigned to the student participants in this study, evolution is 'the process of change that has transformed life on Earth from its earliest beginnings to the diversity of organisms living today' (Reece et al. 2011). Biologists and life science educators have long known that 'nothing in biology makes sense except in light of evolution' (Dobzhansky 1973). Evolution is supported by evidence from many sources, from genetics to embryology to geology, and it has been directly observed in numerous species in laboratories and in nature. There are no scientifically supported, evidence-based alternative explanations for changes within species or the origin of new species (American Institute of Biological Sciences 1994). Evolution is widely regarded as a central and unifying theme in the biological sciences, and it is presented as such in most modern biology texts (Wiles 2010). Within the scientific community, there is debate over the relative impacts of the known mechanisms by which evolution occurs, but none over whether or not evolution has occurred or continues to happen.

Although evolution has been overwhelmingly accepted by the scientific community (Wiles 2010), evolutionary science has been under essentially continuous social attack even since before Darwin's explanation of evolution by natural selection became widely known in 1859 (Moore 1991). And it remains a hotly-debated political topic, especially regarding its role in science education (Mooney and Nisbet 2005; Wiles 2010). Members of the general public are often unable to differentiate between political and scientific controversy, as despite scientific consensus, political leanings have been shown to influence acceptance of evolution (Allmon 2011; Hawley et al. 2010) which has led to lower rates of acceptance of evolution in the United States as compared to countries in which the issue is less politicized (Miller et al. 2006). It has been suggested that acceptance of evolution may be linked to student achievement (Wiles and Alters 2011), though some may disagree citing the differences between knowing, understanding, and believing (Smith 2009; Southerland et al. 2001).

Edward J. Larson has written a very thorough chronology of court cases related to creationism and evolution in the United States in *Trial and Error: The American Controversy Over Creation and Evolution* (Larson 2002). Among the important events in this history were John Scopes' conviction for teaching evolution, banned in Tennessee by the Butler Act; the subsequent rejection

by the U. S. Supreme Court of the banning of evolutionary instruction in *Epperson v. Arkansas*; the downfall of 'balanced treatment' of so-called 'creation science' and evolution; and the federal overturning of Louisiana's 'Creationism Act', which forbade the teaching of evolution except when accompanied by instruction in 'creation science', in *Edwards v. Aguillard*.

Evolution has become regarded as a cornerstone for education in biology, and is incorporated into the standards for grade school biology recommended by the National Research Council and the Next Generation Science Standards (National Research Council 1996; NGSS Consortium Of Lead States 2013). Evolution has long been considered to be an important part of scientific literacy (American Association for the Advancement of Science 1990, 1993), and it is also considered to be integral in higher education in the biological sciences (Alters and Nelson 2002).

The social controversy continued, however. Amid a growing wake of court decisions barring creationism, 'creation science' and other explicitly religious constructs from public school science classrooms, the creationist opponents to the teaching of evolution began to concoct a more 'scientific' sounding alternative to evolution that they called Intelligent Design (ID) (Pennock and Ruse 2009). As with creation science, bills encouraging the inclusion of ID in curricula do so to help students 'develop critical thinking skills' by 'teaching the controversy' (Brumfiel 2005; Mervis 2011). ID advocacy groups have celebrated the passage of bills allowing teachers to present the 'strengths and weaknesses' of 'controversial' topics like evolution in two U.S. states, Louisiana and Tennessee, in the past several years (Thompson 2012) despite opposition from such groups as the National Center for Science Education.

The evidence is clear, and the scientific community is unified in its assessment of the fact of evolution. Science educators are resolute in their insistence that evolution be taught as a foundational principle of the life sciences. So why, then, do students emerge from our education system largely unknowing and unaccepting of evolution to the point that the political controversy over the teaching of evolution has continued for generations?

There are a number of factors that are thought to affect students' acceptance of evolution, which can be grouped into non-religious and religious factors (Alters and Alters 2001; Wiles and Alters 2011). Per Wiles and Alters (2011) and Wiles (2014) in which they are discussed in greater depth, they may include the following:

### *Non-religious factors*

- Scientific factors
  - Overall knowledge of evolutionary theory
  - Knowledge of evolutionary evidence

- Uncertainty about the origin of life
- Understanding of evolutionary mechanisms and patterns
- Understanding of the nature of science
- Non-scientific factors
  - Social and emotional factors (for example, personal relationships, authorities, fear, or discomfort with perceived implications of evolution)
  - Critical thinking skills, epistemological views, and cognitive dispositions
  - Demographic factors (for example, academic standing, political leanings)

#### *Religious factors*

- Perception that religious belief and acceptance of evolution are mutually exclusive
- Literal interpretation of scripture
- Creationist convictions
- Labeling of religious doctrine as scientific (for example, 'creation science' and ID)

A few studies have shown that presenting students with a direct comparison of the misconceptions about evolution that can result from these factors (or indeed be intentionally perpetuated by creationist groups) can lead to increased acceptance of evolution (Ingram and Nelson 2006; Matthews 2001; McKeachie et al. 2002).

Several studies have suggested that increasing students' understanding of the nature of science (NOS) may enhance their acceptance of evolution (Allmon 2011; Dagher and BouJaoude 1997; Rudolph and Stewart 1998; Sinatra et al. 2003; Smith 2009; Southerland et al. 2001). NOS describes the philosophy of science including how scientific knowledge is generated and how science progresses. Key concepts of NOS include viewing science as more than just the oversimplified, stepwise scientific method presented in many textbooks; the role of the scientific community in the generation of scientific knowledge; the theory laden nature of observation and experimentation; and the fact that scientific theories are durable while science itself is a self-correcting process (Grinnell 2009). Increasing NOS understanding is important in science education in general, as evidenced by its inclusion in the national science education standards (National Research Council 1996), but is predicted to increase acceptance of evolution as students learn about how evidence is considered and the role of consensus in the scientific community. Though many authors suggest that NOS understanding plays a role in the acceptance of evolution, the positive link between changes in NOS conceptions and attitudes towards evolution has, until this study, been poorly understood.

#### **Climate change**

While it was once contentious among scientists, the vast majority of scientists now agree on many aspects of

global climate change (GCC): that it is occurring, that the changes we are observing are most likely due to human influence, and that the changing climate may have other effects such as rising sea levels and changes in the nitrogen cycle (National Research Council 2010). Consensus crosses not only scientific and institutional borders, but political ones as well. The Intergovernmental Panel on Climate Change (IPCC) has produced a number of reports focusing not only on the strength of the science behind GCC, but also on GCC impacts, vulnerability, and mitigation (IPCC 2007, Stocker et al. 2013). Consensus across so many scientific, political, and ideological borders is unprecedented and may speak to the importance of the issues associated with GCC.

Like evolution, GCC is a much more contentious issue politically than it is scientifically. GCC has been a common subject in national polls over the last 20 years (Nisbet and Myers 2007), and these data have been used extensively to document how concern over GCC correlates with different demographic factors, especially whether respondents identify as democrats, republicans, or independents. GCC has been found to be extremely politicized (McCright 2010a), and studies have shown that the gap in GCC concern between Democrats and Republicans has increased markedly over the last 10 years (Dunlap and McCright 2008; McCright and Dunlap 2011b). Conservative white men have been shown to be the most likely demographic to deny GCC (McCright and Dunlap 2011a). Somewhat surprising is the presence of strong interaction effects between knowledge about climate change and political identification. That is, among Democrats, GCC concerns increase along with knowledge of GCC, but the same relationship in republicans is weak to negative (Hamilton 2011). The politicization of GCC is most prevalent in the U.S., with cross-national surveys indicating that in most other industrialized nations the views on GCC are much more closely aligned with those of the scientific community (Dispensa and Brulle 2003; Kvaloy et al. 2012).

The political controversies around GCC are surely affecting the teaching of climate science in schools. Like evolution, GCC has been proposed as a central focus in science education because of the scientific consensus behind it coupled with the need for societal action to mitigate its effects (Sharma 2012). This view is shared by many within the science education community including the National Association of Biology teachers who identify GCC as an environmental concept 'particularly relevant to students' everyday lives' (National Association of Biology Teachers 2004) and the National Association of Geoscience Teachers who recognize

- (1) that Earth's climate is changing,
- (2) that present warming trends are largely the result of human activities, and

- (3) that teaching climate change science is a fundamental and integral part of earth science education (National Association of Geoscience Teachers 2008).

And yet, GCC is second only to evolution in topics that educators are unlikely to bring up due to discomfort or fear of controversy (Reardon 2011). Recognizing the need for action in defense of climate change education, the National Center for Science Education (NCSE), an organization well-known known for defending the teaching of evolution, added promotion and protection of the teaching of climate science to its mission. Because attacks on climate change, like those on evolution, rely on misrepresenting climate change denial as being scientifically rather than politically motivated, the NCSE and other groups are concerned that 'teach the controversy' bills will affect education on both issues (Mervis 2011). Strategies for GCC education are still developing, perhaps because it is a much more recent concept than evolution (Cordero et al. 2008; Manolas and Filho 2011; Matkins and Bell 2007; McNeill and Vaughn 2012; National Research Council 2010; Shepardson et al. 2012; Svihla and Linn 2012). The fact that many students and members of the public get most of their knowledge about GCC from the media is additionally problematic. Reporters often have difficulty differentiating between scientific and political controversy, and both evolution and climate change deniers often actively craft their arguments to appear scientific, thereby encouraging this confusion (Dispensa and Brulle 2003). Thus, it has been suggested that training in media literacy, specifically how to critically analyze media coverage to determine sources, bias, and so on, should be an active pursuit in improving understanding and acceptance of GCC (Cooper 2011).

For GCC, 'acceptance' is not a term that is commonly used in the literature (though denial is frequently used). The data on attitudes towards climate change are almost entirely from national surveys, which frame their questions as a sliding scale of concern. However, a number of demographic factors have been shown to correlate with views on GCC. These factors include;

*Scientific factors*

- Knowledge about GCC (either measured or self-declared)

*Non-scientific factors*

- Religiosity
- Demographic factors
  - Political leanings/Party identification
  - Education level
  - Gender (weak but significant correlation)
  - Age
  - Region of residence

(Borick and Rabe 2012; Hamilton and Keim 2009; Hamilton 2011; Marquart-Pyatt et al. 2011; McCright and Dunlap 2011a, 2011b; McCright 2010a, 2010b; Nisbet and Myers 2007).

The abundance of correlations demonstrates that GCC is a very complex issue, with even regional variation in perceptions (Hamilton and Keim 2009). Perhaps bizarrely, one study even found that the presence of healthy *versus* dead plants in the room in which the survey is administered had a significant effect on participants' GCC concerns (Guéguen 2012).

Perhaps the only study has directly linked NOS understanding and GCC revealed that after receiving explicit instruction in both GCC and NOS, education students showed increased understanding of both (Matkins and Bell 2007). The authors concluded that explicit NOS instruction had a positive effect on NOS understanding as well as complex issues of GCC (Matkins and Bell 2007), but given the nature of the study, it would be difficult, if not impossible, to establish NOS instruction as the causal agent of GCC understanding rather than the extensive instruction in GCC. A number of the teaching strategies that have been suggested involve some aspect of NOS, whether it be teaching students the ability to differentiate between scientific and non-scientific items in the media (Cooper 2011) or teaching about how research programs on GCC are put together, including how models are developed (Manolas and Filho 2011).

NOS understanding may play a role in forming students' opinions on GCC, but further research on the topic is clearly warranted. Herein, we present our exploration of this problem as well as how attitudes toward the topic of evolution compare among a sample of university students in an introductory biology course.

## Methods

Although other extant tools for assessing NOS conceptions provide much more robust measurements (Bell and Lederman 2003; Abd-El-Khalick 2001; Lederman 1999), they are decidedly more labor-intensive to score and not easily implemented via the online tools and under the Institutional Review Board guidelines approved for this study. Additionally, these tools do not provide the quantitative output necessary for large-scale statistical comparison. Hence, we chose to measure student conceptions of NOS with the Thinking about Science Survey Instrument (TSSI) (Coburn 2000). The TSSI provided numeric scores for student agreement with nine aspects of the modern model of science. In our final analyses, the sum total of these scores proved to have the most explanatory value, though the score for the 'epistemology' category was a close second. The Measure of Acceptance of the Theory of Evolution (MATE) was employed to assess students attitudes toward evolution, as it has been validated for

measuring acceptance of evolution among various populations (Rutledge and Sadler 2007; Rutledge and Warden 1999), and it has also been used to measure longitudinal change in students' attitudes toward evolution (Wiles and Alters 2011). Since a validated tool for measuring attitudes towards GCC did not exist at the time of this study, student attitudes were measured using questions from national opinion polls (Borick and Rabe 2012; Hamilton and Keim 2009; Hamilton 2011; Leiserowitz et al. 2012; Nisbet and Myers 2007). Demographic questions were generated to measure various factors either shown or suspected to affect attitude towards evolution or GCC. See Additional file 1 for the full list of GCC and demographic questions.

Each survey was administered to a large sample of introductory biology students ( $N = 620$ ) at a large private university in the northeastern US at the beginning and end of the course (with the exception of demographics, which were administered once near the middle of the semester). Some additional questions were added at the end of the course to determine whether important demographic shifts may have occurred (for example, in religious practice or political views) since the previous reporting of these factors. Other variables used in the analysis included a measure of knowledge of evolutionary science (total score on a selection of questions on evolution from the final exam), a measure of knowledge of GCC (total score on a selection of questions on GCC from a quiz produced by NASA (National Aeronautics and Space Administration n.d.)), and a measure of success in the course (the numeric final grade in the biology course).

In order to account for the fact that those students with high scores on the pre-course surveys would have little room for increase, normalized gain was calculated for a number of items, including TSSI total score and MATE score. Normalized gain is calculated by dividing differences in pretest and post-test values by the difference between the pretest value and the maximum possible score, and is frequently used in pretest/post-test analyses (Hake 2002). Principle components analysis (PCA) was used to determine which variables accounted for the majority of variation. Paired t-tests were used to analyze pre-to-post-course differences for individual variables. Finally, ANOVA, along with correlation tests, were used to test for significant correlations, while ANCOVA was used to test for interaction effects with demographic factors.

Student name and ID numbers were removed and replaced with a numeric identifier so that pre- and post-course responses could be paired while maintaining anonymity. The protocols used for this study were approved by the university's Institutional Review Board (IRB).

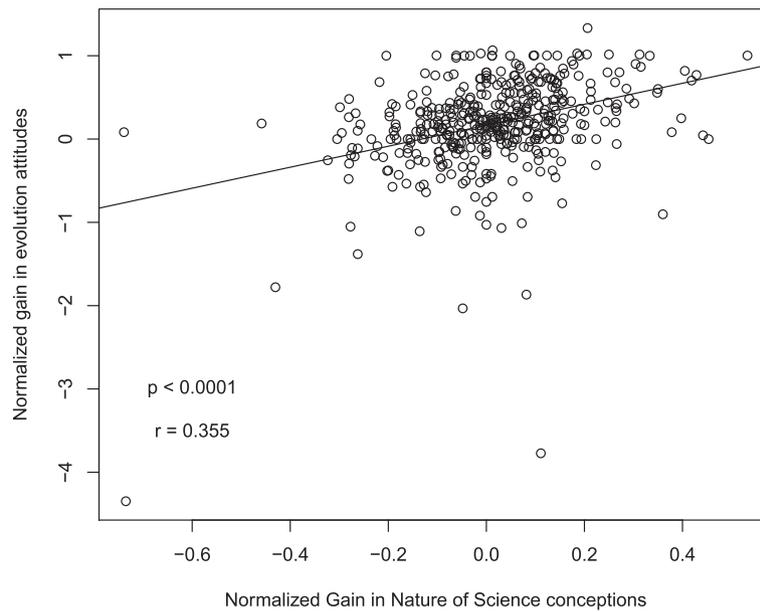

## Results and discussion

From the pre-course surveys, it was clear that this population was different from the U.S. general public. Upwards

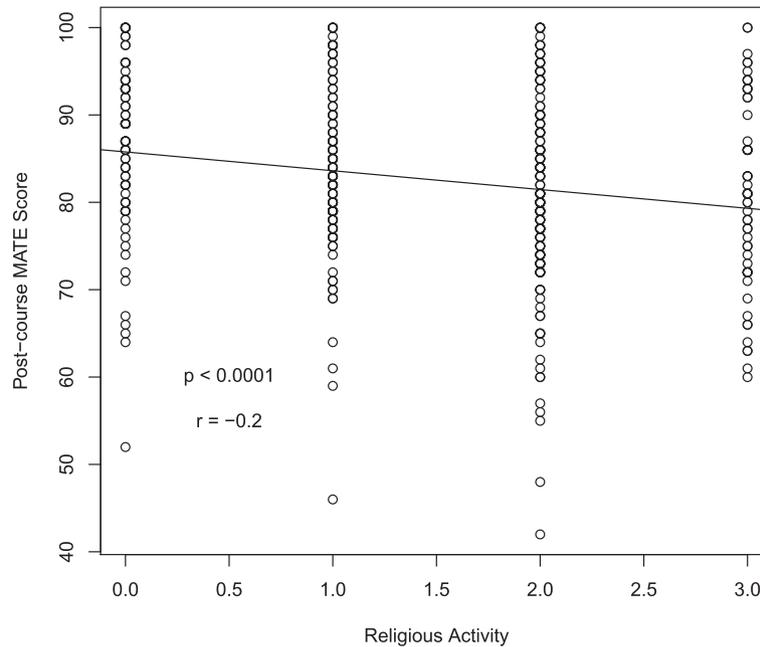

of 60% of respondents scored in the 'high' or 'very high' range of evolution acceptance, while most polls indicate that less than half of the U.S. public believe in evolution. For GCC, results were similar. Nearly 95% of respondents said they believe GCC is occurring (as compared to 66% of the U.S. public). For this reason, for analysis of attitudes towards GCC, we focused on students' levels of personal concern regarding GCC rather than acceptance. Responses on this item were considerably more varied, with about 44% of respondents reporting that the issue was 'very' or 'extremely' important, while about 16% reported that the issue was 'not too' or 'not at all' important. In the U.S. public, 20% said the issue was 'very' or 'extremely' important, while 39% rated GCC as 'not too' or 'not at all' important. It is important to note that while the percentages of students in the low end is low, the overall sample is quite large ( $N = 620$ ), such that the number of students in these lower tiers is actually larger than the entire sample size of many similar studies (for example,  $N = 205$  respondents with acceptance of evolution ranging from 'very low' to 'moderate').

Changes in acceptance of evolution are significantly positively correlated with changes in NOS conceptions, with religiosity as the main demographic factor affecting acceptance. As shown in Figure 1, normalized gains of MATE score and total TSSI score had a correlation of 0.35, and were highly significant ( $P < 0.001$ ). Both pre-course and post-course MATE scores were significantly negatively correlated with religiosity (respondents' Likert-scale responses to the question 'how active do you consider yourself to be in the practice of your religious preference?'). The post-course relationship, shown in Figure 2, was more weakly correlated ( $r = -0.2$ ) than the pre-course relationship ( $r = -0.32$ ), but no less significant ( $P < 0.0001$ ). There was a very small and weakly significant positive correlation between gains in evolution acceptance and reporting an increase in religious activity during the span of the course ( $r = 0.08$ ,  $P = 0.08$ ), which is particularly interesting since the lack of a negative correlation provides evidence against the claim, oft repeated by creationists, that increasing acceptance of evolution leads to decreasing religious belief or activity. As illustrated by Figure 3, post-course evolution acceptance was also significantly positively correlated with knowledge of evolutionary science ( $r = 0.35$ ,  $P < 0.0001$ ), which supports the findings of previous research on this subject (Wiles and Alters 2011).

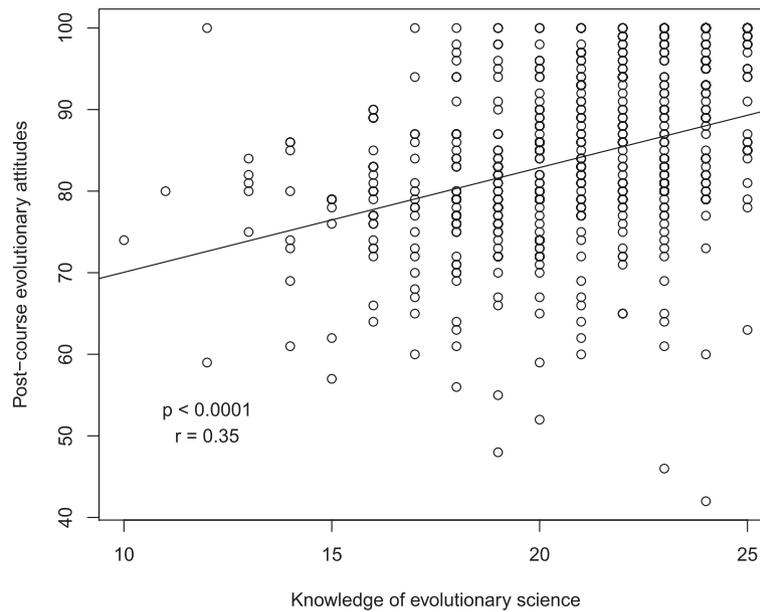

Changes in GCC attitudes also correlate with changes in NOS conceptions. At an alpha of 0.1, changes in personal importance of the issue of climate change are weakly positively correlated with normalized gains in TSSI total score. This comparison is shown in Figure 4, with  $P = 0.065$  and  $r = 0.087$ . Additionally, respondents' scientific view of GCC (a composite of responses to two questions that measured respondents' awareness of the views of the scientific

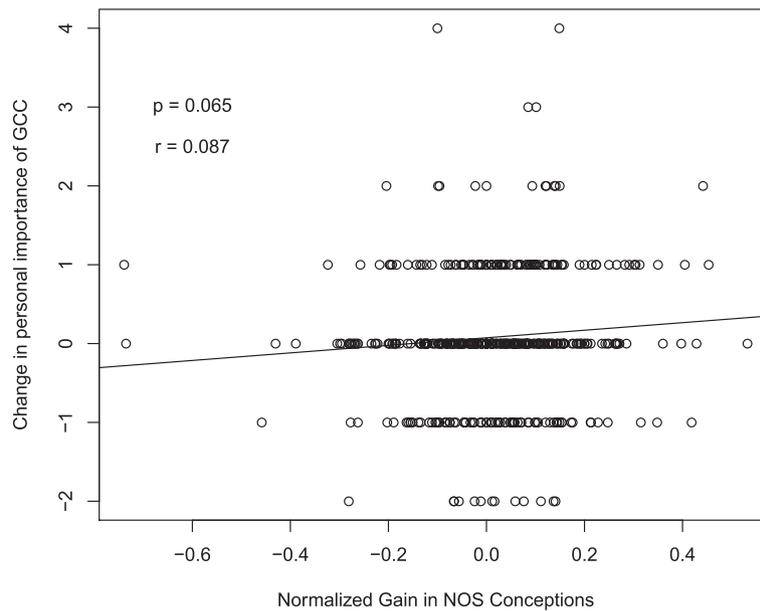

**Figure 1** The relationship between changes in students' NOS conceptions and evolutionary attitudes. Changes in NOS conceptions, as measured by the normalized gains of total scores on the TSSI, are significantly positively correlated with changes in attitudes towards evolution, measured by normalized gains of total scores on the MATE tool. The value of  $r$  indicated in the figure (0.355), is Pearson's correlation coefficient for the two variables.

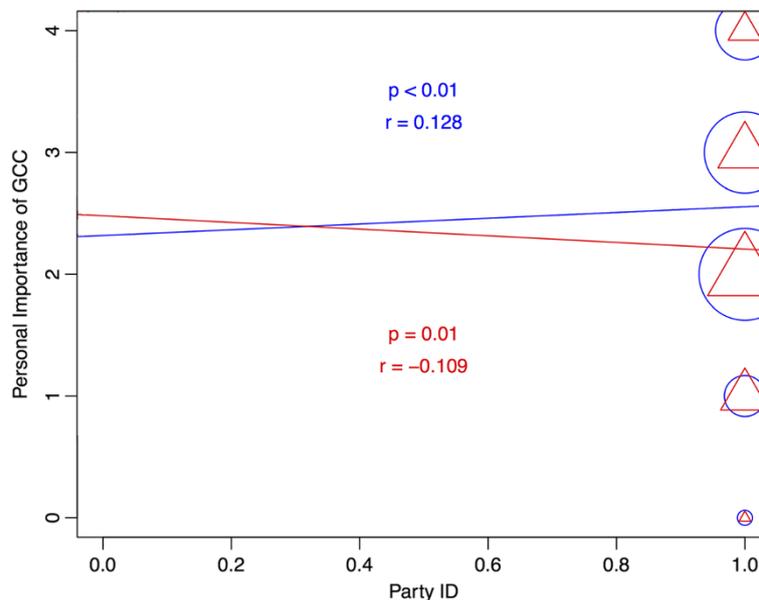

**Figure 2** The relationship between students' post-course evolutionary attitudes and religiosity. Student attitudes towards evolution, as measured by their post-course total score on the MATE tool, are negatively correlated with religiosity, here a Likert-scale response to the question 'how active would you say you are in the practice of your religious preference?' This factor has four levels, ranging from zero (not active) to three (very active). The value of  $r$  indicated in the figure ( $-0.2$ ), is Pearson's correlation coefficient for the two variables.

**Figure 3** The relationship between students' post-course evolutionary attitudes and knowledge of evolutionary science. Student attitudes towards evolution, as measured by their post-course total score on the MATE tool, are positively correlated with knowledge of evolutionary science. The latter was measured using a subset of questions from the course final exam which pertained directly to the science of evolution. The value of  $r$  indicated in the figure (0.35), is Pearson's correlation coefficient for the two variables.

**Figure 4** Relationship between changes in students' attitudes towards GCC and conceptions about NOS. At an alpha of 0.1, changes in how important the issue of GCC was to students had a weak positive correlation with changes in nature of science conceptions, measured by the normalized gains of total scores on the TSSI. The value of  $r$  indicated in the figure (0.087), is Pearson's correlation coefficient for the two variables.

**Figure 5** The relationship between students' political party identification and personal importance of GCC. In this figure, blue circles and the blue positive trend line represent the relationship between post-course personal importance of GCC and identification as a Democrat. Red triangles and the red negative trend line represent the relationship between post-course personal importance of GCC and identification as a Republican. The sizes of the symbols increase with increasing number of overlapping data points so that their distribution can be more easily visualized. Here the trends are essentially opposite for students identifying with the two parties, with a positive Pearson's correlation coefficient (0.128) for Democrats, and a negative one (-0.109) for Republicans. It is important to note, however, that the two variables were more weakly correlated, for both Democrats and Republicans, when comparing post-course attitudes towards climate change rather than pre-course attitudes.

community on GCC) were not significantly correlated with NOS conceptions in the pre-course surveys, but were correlated in post-course surveys, with  $r = 0.118$  with  $P < 0.01$ , which may be linked to NOS conceptions having to do with scientific consensus and the treatment of evidence. Interestingly, knowledge about GCC was not significantly correlated with attitudes towards GCC.

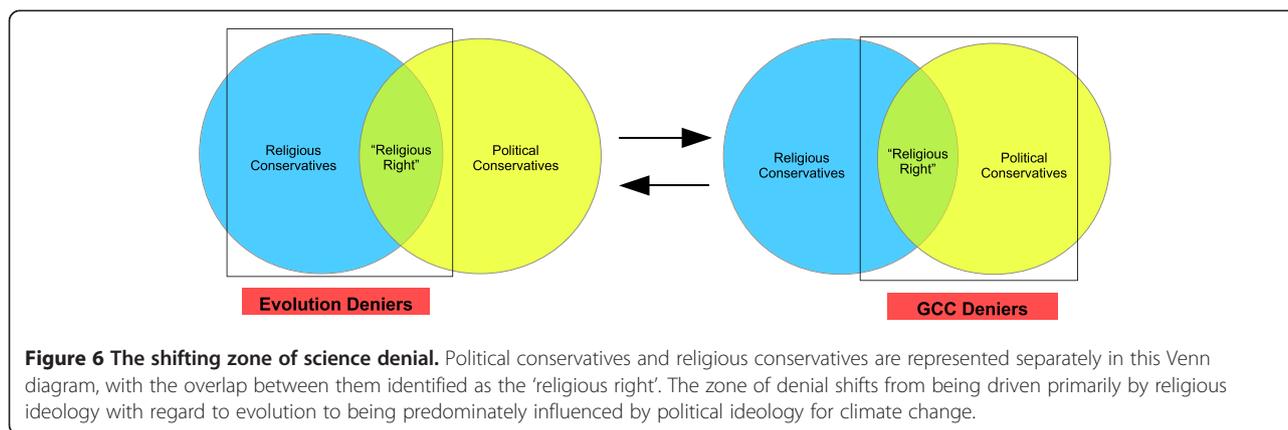

In both pre- and post-course surveys, personal importance of GCC is most strongly correlated with political leanings, that is, negatively correlated with conservatism. Interestingly, that correlation does become weaker, though no less significant, from the first to second survey; pre-course  $r = -0.215$  with  $P < 0.0001$  while post-course,  $r = -0.171$  with  $P < 0.0001$ . The trend is also present when examining political party affiliations. As shown in Figure 5, identifying as a democrat is positively correlated with GCC importance ( $r = 0.113$ ,  $P < 0.01$ ), while identifying as a republican is negatively correlated with GCC importance ( $r = -0.11$ ,  $P < 0.05$ ).

## Conclusions

In this study, changes in evolution acceptance and changes in attitudes towards GCC do correlate positively with changes in NOS conceptions. These findings support the hypothesis that a better understanding of the modern model of science may lead to changes in attitudes towards

politically contentious ideas that are not scientifically contentious. However, the data indicate that correlations differ between evolution and climate change. Of all the measured variables in this study, measures of political views were most highly correlated with attitudes towards GCC. More conservative political views, especially fiscal conservatism, correlated negatively with personal importance of the issue of climate change. Broken down among party lines, correlations between party identification and importance of GCC were almost exactly opposite (for republicans,  $r = -0.11$  while for democrats  $r = +0.13$ ). Interestingly, party leanings do NOT significantly correlate with changes in GCC attitudes, which could indicate a lack of large enough changes in GCC attitudes to measure. A paired t-test indicates a mean difference of just 0.06 between pre- and post-course measurements for a factor with five levels. The lack of difference is not surprising, given the fact that there is considerably less direct instruction on GCC in the course than there is on evolution.

Not only were GCC importance and concern most strongly correlated with political views, but of the GCC deniers in our sample, over two-thirds identified politically as fiscal conservatives. Unsurprisingly, evolution rejection was most strongly correlated with religious factors. However, GCC deniers in this study tended not to be highly religious or affiliated with conservative denominations.

These results are consistent with data from a Pew Research Center (2009) poll which found that the strongest predictor of climate change denial is political affiliation, with political conservatives being more likely to deny GCC than other groups. The same poll also found that religious conservatism, whether measured by denominational affiliation or degree of religiosity, was the strongest correlate of evolution denial. Religious conservatism does not map perfectly onto political conservatism, but there is certainly an area of overlap known as the 'religious right'. Similarly, rejection of evolution does not always predict rejection of GCC. Figure 6 illustrates this, as the 'zone of denial' shifts from religious to political conservatism as it moves from rejection of evolution to rejection of GCC.

The lack of correlation between changes in evolution acceptance and changes in religious activity counters the idea that belief in evolution and religion are mutually exclusive, one of the 'pillars of creationism' according to the National Center for Science Education (National Center for Science Education 2008). That is to say, becoming more accepting of evolution does not necessarily mean becoming less religiously active, or vice versa. Actually, a very slight positive relationship between the two was measured among this population.

This study has various important implications. First, giving students a good conception of the modern NOS may lead to views that are more in line with those of the scientific community. Of course, further research is required to establish the direction of causation, but it is difficult to imagine how becoming more concerned about climate change could cause a more scientific epistemology or a better understanding of scientific methodology. Second, while evolution is thought of as a politically contentious topic, as is the case currently in Louisiana, attitudes towards GCC are much more related to political views in this study population. The fact that these correlations do decrease over the span of the course, however, is heartening. A greater emphasis on GCC (and NOS) may even lead to the disappearance of this correlation entirely.

Finally, this study represents the first concrete evidence of a linkage between acceptance of evolution and attitudes towards GCC, that is, NOS conceptions.

Future research on this topic should involve multiple institutions, comparing universities of different types, sizes, and geographic locations. More robust measures of NOS conceptions should be employed where possible, and qualitative methods such as interviews could be used to help determine the direction of causation for the various correlations discovered in this study. Students with large gains in evolution acceptance should be interviewed to determine how those changes came about.

ANCOVA: Analysis of covariance; ANOVA: Analysis of variance; GCC: Global climate change; ID: Intelligent Design; IRB: Institutional review board; MATE: Measure of acceptance of the theory of evolution; NASA: National Aeronautics and Space Administration; NOS: Nature of science; PCA: Principle components analysis; TSSI: Thinking about science survey instrument.

#### Competing interests

The authors declare that they have no competing interests.

#### Authors' contributions

BEC collected and analyzed survey data, wrote demographic questions, generated figures, and drafted the manuscript. JRW helped conceptualize and design the study, provided numerous resources for data collection, and revised the manuscript critically for important intellectual content. Both authors read and approved the final manuscript.

#### Authors' information

BEC is pursuing a Ph.D. in college science teaching at Syracuse University. JRW is a biology professor at Syracuse University and holds secondary appointments in the Syracuse University departments of Earth Science and Science Teaching.

#### Acknowledgements

The authors offer sincere thanks to Bev Werner for her help with the logistics of electronic administration of surveys as well as anonymizing them. BEC thanks Caitlin Conn for her feedback on drafts of the manuscript. The authors also thank Eugenie Scott for her original conception of the shifting zone of science denial among conservatives, anonymous reviewers for

helpful editorial comments, and Josh Rosenau for help with data processing and key information from public opinion polls.
